Editorial 🔒

Flatland is a country with n cities, m of which have space stations. Its cities (c) are numbered from 0 to $n - 1$, where i^{th} city is referred to as c_i .

Between each c_i and c_{i+1} (where $0 \leq i < n$), there exists a bidirectional road 1 km long.

For example, if $n = 5$ and cities c_0 and c_4 have space stations, Flatland would look like this:

For each city, determine its distance to the *nearest* space station and *print the maximum* of these distances.

Input Format

The first line consists of two space-separated integers, n and m .

The second line contains m space-separated integers c_0, c_1, \dots, c_{m-1} denoting the index of each city having a space station. These values are *unordered* and unique.

Constraints

$$1 \leq n \leq 10^5$$

$$1 \leq m \leq n$$

Note: There will be at least 1 city with a space station, and no city has more than one.

Output Format

Print an integer denoting the maximum distance that an astronaut in a Flatland city would need to travel to reach the nearest space station.

Sample Input 0:

```
5 2
0 4
```

Input Output 0:

```
2
```

Sample Input 1:

```
6 6
0 1 2 4 3 5
```

Input Output 1:

0

Explanation**Sample 0:**

This sample corresponds to the example given in the problem statement above. The distance to the nearest space station for each city is listed below:

- c_0 has distance **0 km**, as it contains a space station.
- c_1 has distance **1 km** to the space station in c_0 .
- c_2 has distance **2 km** to the space stations in c_0 and c_4 .
- c_3 has distance **1 km** to the space station in c_4 .
- c_4 has distance **0 km**, as it contains a space station.

We then take $\max(0, 1, 2, 1, 0) = 2$, and print **2** as our answer.

Sample 1:

In this sample, $n = m$ so every city has space station and we print **0** as our answer.
